Midterm Examination

NAME:			
STUDENT ID:			

HONOR CODE: As a member of the SUTD community, I pledge to always uphold honorable conduct. I will be accountable for my words and actions, and be respectful to those around me. All work turned in for this test is solely my own and I take pride in this.

SIGNATURE:		

- The exam is 1 hour and 45 minutes in duration.
- There are a total of 30 questions, each carrying one point.
- Answer all the questions in the boxes provided. You do NOT need to write your R commands, or any justification in the answer sheet unless they are specifically asked for.
- The data sets are available in the e-dimension course content folder at the link Mid-term.
- For your work, you may use an R-script, R-markdown or just an R session. Immediately at the end of the exam, save your R-file.
 - To do this go to File > Save as > "Yourname_IDnumber.R", or,
 - "Yourname_IDnumber.txt", or, "Yourname_IDnumber.Rmd".
 - Upload the files via the Mid-term link on e-dimension.
 - If the link does not work send the files to bikram@sutd.edu.sg.
 - This will be used only to validate that your work is original.
- You are allowed to use only the notes from the lectures (associated paper, book, slides) and R for this exam.
- The use of the Internet and mobilephones are NOT permitted.
- Good luck!

1. (16 points) Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for the year 1960. The data set USCrime.csv contains the following columns:

Variable	Description
М	percentage of males aged 14–24 in total state population
So	indicator variable for a southern state (binary variable)
Ed	mean years of schooling of the population aged 25 years or over
Po1	per capita expenditure on police protection in 1960 (in US \$)
Po2	per capita expenditure on police protection in 1959 (in US \$)
LF	labour force participation rate of civilian urban males in the age-group 14-24
M.F	number of males per 100 females
Pop	state population in 1960 in hundred thousands
NW	percentage of nonwhites in the population
U1	unemployment rate of urban males aged 14–24
U2	unemployment rate of urban males aged 35–39
Wealth	wealth: median value of transferable assets or family income (in US \$)
Ineq	income inequality: percentage of families earning below half the median income
Prob	probability of imprisonment: ratio of number of commitments to number of offenses
Time	average time in months served by offenders in state prisons before their first release
Crime	crime rate : number of offenses per 100,000 population in 1960
States	two letter code for the state name

Our goal in this study is to find which factors affect crime rate using this dataset.

(a)	Read the data into the dataframe UScrime. Which state has the lowest and which state has the highest crime rates respectively?

(b)	Find the average crime rate (Crime) in states where per capita expenditure on politection in 1960 was above US\$ 8. Also find the average crime rate for states who capita expenditure on police protection in 1960 was less than or equal to US\$ 8.
(c)	Run a two-sample t-test to verify if there is any difference in crime rates for states sp more than US \$ 8 per month and states spending less than or equal to US \$ 8 per on police protection (both for the year 1960). Write down the null hypothesis for yo
(d)	For the test conducted in part (c) write down the p-value and your conclusion.

	against their per capita expenditure on police protection in 1960.
	What is the R-squared for your model?
(f)	Create a test dataset by choosing the 43rd to 47th states (VA, WA, WV, WI, WY). Call this dataset UStest (remove the States variable as before). What is the 99% confidence
(f)	,
(f)	this dataset UStest (remove the States variable as before). What is the 99% confidence interval for the predicted crime rate for Washington (WA) using the model from part (e)?
(f)	this dataset UStest (remove the States variable as before). What is the 99% confidence interval for the predicted crime rate for Washington (WA) using the model from part (e)?
(f)	this dataset UStest (remove the States variable as before). What is the 99% confidence interval for the predicted crime rate for Washington (WA) using the model from part (e)?
(f)	this dataset UStest (remove the States variable as before). What is the 99% confidence interval for the predicted crime rate for Washington (WA) using the model from part (e)?

g)	What is the 99% confidence interval for the predicted crime rate for Wisconsin (WI) using the same model? Is the actual crime rate value within this interval?
	Now develop a multiple linear regression model with the dataset UStrain to predict Crime rates using all available predictor variables (and intercept). Which variables are significant at 0.05 level and what is the R-squared for this model?
	Using only the variables that you found significant at 0.05 level (p-value less than 0.05) in the previous model in part (h), create a new linear regression model on the UStrain data set. What is the R-squared for the new model?

x) We now use	e the regsubse	ets() function	n in the leaps	package for a	best subset select
How many	_	ncluded in the	=		best subset select squared to pick y
How many	variables are i	ncluded in the	=		
How many	variables are i	ncluded in the	=		
How many	variables are i	ncluded in the	=		
How many	variables are i	ncluded in the	=		

(1)	Another criterion for selecting models that is often used is Bayesian information criterion (BIC). For a model with n observations and k parameters where $\hat{\beta}$ is the least-squares estimate of the model parameter β , it is defined as
	$BIC = k \log(n) - 2 \log(\text{likelihood}(\hat{\beta})).$
	Lower BIC values are preferred to higher BIC values. BIC is provided as an output of regsubsets() called bic. How many variables are included in the model if you use BIC to pick your model with best subset selection (use the UStrain data set)?
m)	How many variables are included in the model if you use BIC to pick your model with forward stepwise selection (use the UStrain data set)?

(n)	Now using UStest set for your out-of-sample validation, you are asked to choose one of the models from parts (k), (l), and (m). Create separate multiple linear regression models using the predictors found in parts (k), (l) and (m). Use these models to find the sum-of-squared errors (SSE) for the UStest data set. What is the test set SSE for the model in part (k)?
(o)	What are the test set SSEs for the models in parts (l) and (m)?
(p)	Which model do you prefer among the ones created in parts (k), (l) and (m) based on your findings above?

2. (14 points) Record labels often face a decision problem of which musical releases to support to maximize their financial success. In this question our goal is to predict whether a song will reach a spot in the **Top 10** of the Billboard Hot 100 Chart. Taking an analytics approach, we aim to use information about a song's properties to predict its popularity. The dataset songs.csv consists of all songs which made it to the **Top 10** of the Billboard Hot 100 Chart from 1990–2010 plus a sample of additional songs that didn't make the **Top 10**.

The variables included in the dataset either describe the artist or the song, or they are associated with the following song attributes: time signature, loudness, key, pitch, tempo, and timbre. Here's a detailed description of the variables:

- year = the year the song was released;
- songtitle = the title of the song;
- artistname = the name of the artist of the song;
- songID and artistID = identifying variables for the song and artist;
- timesignature and timesignature_confidence = a variable estimating the time signature of the song, and the confidence in the estimate;
- loudness = a continuous variable indicating the average amplitude of the audio in decibels;
- tempo and tempo_confidence = a variable indicating the estimated beats per minute of the song, and the confidence in the estimate;
- key and key_confidence = a variable with twelve levels indicating the estimated key of the song (C, C#, . . ., B), and the confidence in the estimate;
- energy = a variable that represents the overall acoustic energy of the song, using a mix
 of features such as loudness;
- pitch = a continuous variable that indicates the pitch of the song;
- timbre_0_min, timbre_0_max, timbre_1_min, timbre_1_max, ..., timbre_11_min, and timbre_11_max = variables that indicate the minimum/maximum values over all segments for each of the twelve values in the timbre vector (resulting in 24 continuous variables);
- Top10 = a binary variable indicating whether or not the song made it to the Top 10 of the Billboard Hot 100 Chart (1 if it was in the top 10, and 0 if it was not).

Note that time_signature is a discrete variable. What are the values taken by time_signary and what are the frequency of occurrences of each value in the dataset? We would like to predict if a song makes it to the Top 10 chart. The outcome is listed in the variable Top10. Create a training set SongsTrain with observations up to and including 2008 releases and a testing set SongsTest consisting of 2009 and 2010 song releases. How many observations (songs) are in the test set?

(1)	namely, probit regression where the equation to be estimated is given
	$\Pr(Y=1) = \Phi(\beta_0 + \beta_1 x_1 + \ldots + \beta_p)$
	where Φ is the standard normal cumulative distribution function. Build this model using the data set SongsTrain, which we call Model 4 with only the statistically significant predictors (at level 0.05) that you identified while building Model 3 on SongsTrain. Hint: You can fit the model by using glm by modifying the family argument with family = binomial(link="probit"). Write down the accuracy for the probit fit with a threshold of 0.40 on the test data set SongsTest.
(m)	What are the sensitivity and specificity values you obtain using Model 4 on the SongsTes data with threshold 0.40?
